Tutorial 11 - Expectation Maximization (EM Algorithm)

• Based on Pattern Recognition and Machine Learning by Christopher Bishop (chapter 9) and slides by Shai Fine

Agenda

- Demonstrations
 - K-means
 - Gaussian Mixture Models (GMM)
- Expectation-Maximization
 - Formalization
 - EM Algorithm
- · Gaussian Mixture Models (GMM)
 - Overview
- · Bernoulli Mixture Model (BMM)
- K-means as "Hard GMM"

Demonstrations

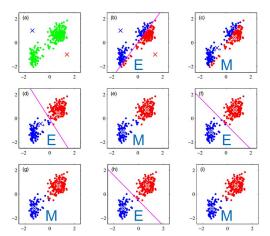

- Definitions
 - Hard Clustering clusters do not overlap, an element either belongs to a cluster or does not.
 - Soft Clustering clusters may overlap. Strength of association between clusters and instances (confidence level).

K-Means

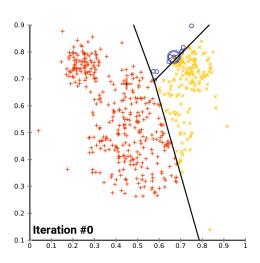

- K-means clustering is one of the simplest and popular unsupervised machine learning algorithms.
 - Typically, unsupervised algorithms make inferences from datasets using only input vectors without referring to known, or labeled, outcomes.
- The objective of K-means: group similar data points together and discover underlying patterns. To achieve this objective, K-means looks for a fixed number (k) of clusters in a dataset.
 - This is also called hard clustering as the association of a data point to a cluster is definitive, that is, it belongs to one cluster only and cannot be included in other cluster.
- · A cluster refers to a collection of data points aggregated together because of certain similarities.

• Illustration:

■ E and M stand for the E-step and M-step

· Animation:

- Algorithm: Starts with a first group of randomly selected centroids, which are used as the starting points for every cluster, and then performs iterative (repetitive) calculations to optimize the positions of the centroids. It halts creating and optimizing clusters when either:
 - The centroids have stabilized—there is no change in their values because the clustering has been successful.
 - The defined number of iterations has been achieved.

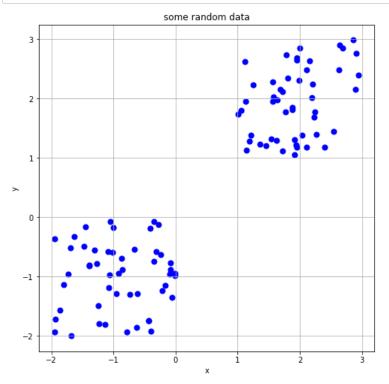

Explanations and example from <u>Understanding K-Means Clustering in Machine Learning - towardsdatascience.com</u> (https://towardsdatascience.com/understanding-k-means-clustering-in-machine-learning-6a6e67336aa1).

Gaussian Mixture Models (GMMs)

- · A Gaussian mixture model is a probabilistic model that assumes all the data points are generated from a mixture of a finite number of Gaussian distributions with unknown parameters.
 - That is, we consider a family of models, $p_0(x)$, which is a weighted sum k Gaussian functions, where each Gaussian can have different mean and co-variance matrix.
- · One can think of mixture models as generalizing k-means clustering to incorporate information about the co-variance structure of the data as well as the centers of the latent Gaussians.
- The parameters of the model are the mean, co-variance and weight of each Gaussian, which are unknown and will be learned by the EM algorithm.
 - The parameters: $\theta = \{\pi_l, \mu_l, \Sigma_l\}_{l=1}^k$ (π is the weight vector).
 - In other words- "with probability π_l draw the sample from l^{th} Gaussian".
- Goal: Soft clustering the data under the assumption that it is generated by a mixture of Gaussians.
 - The optimization method is called Expectation Maximization (EM) and will be used to achieve this goal.

    plot_gmm(gmm, X, ax=ax)
```

In [14]: run_plot_gmm(X)

Expectation Maximization (EM)

- · Probabilistic method for soft clustering.
 - The "soft" version of K-means
- Assumes a probabilistic model of clusters that allows computing $Pr(c_j|x)$ for each cluster c_j for a given example x.
 - If we had known for each data instance from what distribution it came from, we could have used a parametric estimation.
- We introduce unobservable (latent) variables which indicate source distribution.
- · We run an iterative process:
 - Estimate latent variables from the data and the *current* estimation of distribution parameters.
 - Use current values of latent variables to refine parameter estimation.

Formalization

• Log likelihood for a mixture model (under the i.i.d assumption):

$$\mathcal{L}(X|\Theta) = \log \prod_{i=1}^{n} Pr(x_i|\Theta) = \sum_{i=1}^{n} \log \sum_{j=1}^{k} Pr(x_i|C_j;\Theta) Pr(C_j;\Theta)$$

- Assume latent variables z, which when known make the optimization simpler:
 - Complete likelihood, $\mathcal{L}_c(X, Z | \Theta)$, in terms of x and z
 - **Incomplete** likelihood, $\mathcal{L}(X|\Theta)$, in terms of x
- However, z is *latent*, so we **can't compute** $\mathcal{L}_c(X, Z|\Theta)$
 - But we can compute its **conditional expected value**, given X and old θ^t :

$$Q(\Theta; \Theta^{t}) = \mathbb{E}_{Z}[\mathcal{L}_{c}(X, Z | \Theta) | X, \Theta^{t})] = \sum_{Z} Pr(Z | X, \Theta^{t}) \log Pr(X, Z; \Theta)$$

- From a computation viewpoint:
 - The E-Step: computes the posterior probability $Pr(Z|X, \Theta^l)$ using the *current* estimates (probability point i belongs to model j)
 - The M-Step: updates the parameter estimates to get Θ^{t+1} by maximizing $Q(\Theta; \Theta^t)$
- The EM Algorithm requires an **initial guess** Θ^0 for the parameters.
- Each iteration of E-step and M-step is **guaranteed to increase the log-likelihood** of the observed data, $logPr(X|\Theta)$ until a *local* maximum is reached.

· Iterate the two steps:

■ E-step: Estimate Z given X and current Θ

$$\circ \ \ Q(\Theta \,|\, \Theta^t) = \mathrm{E}[\mathcal{L}(X,Z \,|\, \Theta) \,|\, X,\Theta^t]$$

■ **M-step**: Find new Θ given Z, X and old Θ

$$\bullet \ \Theta^{t+1} = argmax_{\Theta}Q(\Theta; \Theta^t)$$

• An increase in Q increases the incomplete likelihood

$$\mathcal{L}(X|\Theta^t) \geq Q(\Theta|\Theta^t)$$

Proof (Important):

• Denote the prior of z for the i^{th} sample: $q_i(z)$

$$\mathcal{L}(X|\theta) = \sum_{i=1}^{n} \log\left[\sum_{z_i} p(x_i, z_i|\theta)\right] = \sum_{i=1}^{n} \log\left[\sum_{z_i} q_i(z_i) \frac{p(x_i, z_i|\theta)}{q_i(z_i)}\right] = \sum_{i=1}^{n} \log\left[\mathbb{E}_{z \sim q_i} \left(\frac{p(x_i, z|\theta)}{q_i(z)}\right)\right]$$

• Since log is concave we use Jensen's inequality to derive the following lower bound:

$$\mathcal{L}(X|\theta) = \sum_{i=1}^{n} \log \left[\mathbb{E}_{z \sim q_i} \left(\frac{p(x_i, z \mid \theta)}{q_i(z)} \right) \right] \ge \sum_{i=1}^{n} \mathbb{E}_{z \sim q_i} \log \left[\frac{p(x_i, z \mid \theta)}{q_i(z)} \right] = \mathcal{F}(\theta, \{q_i(\cdot)\}_{i=1}^n)$$

• This is true for every choice of q, and in particular for $q_i(z) = p(z | x_i, \theta)$:

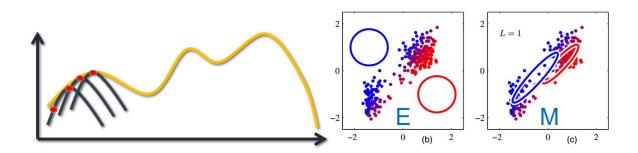

$$\mathcal{L}(X|\theta) \ge \sum_{i=1}^{n} \mathbf{E}_{z \sim p(z|x_{i},\theta)} \log \left[\frac{p(x_{i},z|\theta)}{p(z|x_{i},\theta)} \right]$$

- Notice that this equals: $\mathcal{F}(\theta, \{q_i(\cdot)\}_{i=1}^n) = \sum_{i=1}^n \mathbb{E}_{z \sim p(z|x_i, \theta)} \log(p(x_i|\theta)) = \sum_{i=1}^n \log p(x_i|\theta) = \mathcal{L}(X|\theta)$ (the first transition is due to the expectation on z, not on x), which means the **lower bound becomes equality**.
- · Let's continue:

$$\mathcal{L}(X|\theta) \geq \sum_{i=1}^{n} \mathbb{E}_{z \sim q_{i}} \log \left[\frac{p(x_{i}, z \mid \theta)}{q_{i}(z)} \right] = \sum_{i=1}^{n} \mathbb{E}_{z \sim q_{i}} \left[\log p(x_{i}, z \mid \theta) - \log q_{i}(z) \right] = \sum_{i=1}^{n} \left[\mathbb{E}_{z \sim q_{i}} \log p(x_{i}, z \mid \theta) - \mathbb{E}_{z \sim q_{i}} \log q_{i}(z) \right] = \sum_{i=1}^{n} \left[\mathbb{E}_{z \sim q_{i}} \log p(x_{i}, z \mid \theta) + \mathcal{H}(q_{i}(z)) \right] \geq \sum_{i=1}^{n} \left[\mathbb{E}_{z \sim q_{i}} \log p(x_{i}, z \mid \theta) - \mathbb{E}_{z \sim q_{i}} \log q_{i}(z) \right] = \sum_{i=1}^{n} \left[\mathbb{E}_{z \sim q_{i}} \log p(x_{i}, z \mid \theta) - \mathbb{E}_{z \sim q_{i}} \log q_{i}(z) \right] = \sum_{i=1}^{n} \left[\mathbb{E}_{z \sim q_{i}} \log p(x_{i}, z \mid \theta) - \mathbb{E}_{z \sim q_{i}} \log q_{i}(z) \right] = \sum_{i=1}^{n} \left[\mathbb{E}_{z \sim q_{i}} \log p(x_{i}, z \mid \theta) - \mathbb{E}_{z \sim q_{i}} \log q_{i}(z) \right] = \sum_{i=1}^{n} \left[\mathbb{E}_{z \sim q_{i}} \log p(x_{i}, z \mid \theta) - \mathbb{E}_{z \sim q_{i}} \log q_{i}(z) \right] = \sum_{i=1}^{n} \left[\mathbb{E}_{z \sim q_{i}} \log p(x_{i}, z \mid \theta) - \mathbb{E}_{z \sim q_{i}} \log q_{i}(z) \right] = \sum_{i=1}^{n} \left[\mathbb{E}_{z \sim q_{i}} \log p(x_{i}, z \mid \theta) - \mathbb{E}_{z \sim q_{i}} \log q_{i}(z) \right] = \sum_{i=1}^{n} \left[\mathbb{E}_{z \sim q_{i}} \log p(x_{i}, z \mid \theta) - \mathbb{E}_{z \sim q_{i}} \log q_{i}(z) \right] = \sum_{i=1}^{n} \left[\mathbb{E}_{z \sim q_{i}} \log p(x_{i}, z \mid \theta) - \mathbb{E}_{z \sim q_{i}} \log q_{i}(z) \right] = \sum_{i=1}^{n} \left[\mathbb{E}_{z \sim q_{i}} \log p(x_{i}, z \mid \theta) - \mathbb{E}_{z \sim q_{i}} \log q_{i}(z) \right] = \sum_{i=1}^{n} \left[\mathbb{E}_{z \sim q_{i}} \log p(x_{i}, z \mid \theta) - \mathbb{E}_{z \sim q_{i}} \log q_{i}(z) \right] = \sum_{i=1}^{n} \left[\mathbb{E}_{z \sim q_{i}} \log p(x_{i}, z \mid \theta) - \mathbb{E}_{z \sim q_{i}} \log q_{i}(z) \right] = \sum_{i=1}^{n} \left[\mathbb{E}_{z \sim q_{i}} \log p(x_{i}, z \mid \theta) - \mathbb{E}_{z \sim q_{i}} \log q_{i}(z) \right] = \sum_{i=1}^{n} \left[\mathbb{E}_{z \sim q_{i}} \log p(x_{i}, z \mid \theta) - \mathbb{E}_{z \sim q_{i}} \log q_{i}(z) \right]$$

• $\mathcal{H}(q_i(z))$ - the **entropy** of $q_i(z)$, which **does not depend on** θ . Thus, taking the $argmax_{\theta}$:

$$argmax_{\theta} \sum_{i=1}^{n} \left[\mathbb{E}_{z \sim q_{i}} \log p(x_{i}, z \mid \theta) + \mathcal{H}(q_{i}(z)) \right] = argmax_{\theta} \mathcal{Q}(\Theta; \Theta')$$

Algorithm 1 The EM algorithm

1: Initialize:

 θ

2: while θ not converged do

3:
$$\forall x_i \in \mathcal{D}, z_l \in z, \ q_i^*(\cdot) \leftarrow p(z_l \mid x_i, \theta)$$

4:
$$\theta^{t+1} = \arg\max_{\theta} \sum_{i=1}^{n} E_{z \sim q_i^*(\cdot)} \left[\log p(x_i, z \mid \theta) \right]$$

5: end while

6: return θ

Exercise - Improvement of the EM Algorithm

Prove that in each iteration the EM algorithm improves, i.e., that the likelihood in each iteration increases or the algorithm halts.

- Solution

Consider the value of the log-likelihood after t-1 time-steps $\mathcal{L}(X|\theta^{t-1})$. At this point, we perform the **E** (expectation) step in which we choose $q_i(z) = p(z|x_i, \theta)$, thus:

$$\mathcal{L}(X|\theta^{t-1}) = \mathcal{F}(\theta^{t-1}, \{q_i(\cdot)\}_{i=1}^n)$$

• We saw that earlier.

Now, by definition, when we maximize an expression as we do in the M (maximization) step, we get:

$$\mathcal{F}(\theta^t, \left\{q_i(\,\cdot\,)\right\}_{i=1}^n) \geq \mathcal{F}(\theta^{t-1}, \left\{q_i(\,\cdot\,)\right\}_{i=1}^n)$$

Or more specifically:

$$Q(\Theta \mid \Theta^t) \ge Q(\Theta \mid \Theta^{t-1})$$

Finally, recall that:

$$\mathcal{L}(X|\theta^t) \ge \mathcal{F}(\theta^t, \{q_i(\cdot)\}_{i=1}^n) \ge Q(\Theta; \Theta^t)$$

And putting it all together:

$$\mathcal{L}(X|\theta^{t-1}) = \mathcal{F}(\theta^{t-1}, \{q_i(\cdot)\}_{i=1}^n) \le \mathcal{F}(\theta^t, \{q_i(\cdot)\}_{i=1}^n) \le \mathcal{L}(X|\theta^t)$$

E

E Step - EM Receipe

Estimate Z given X and current Θ (the **posterior**):

$$Pr(z_i = j \mid x_i, \Theta) = r_{ij} = \frac{Pr(x_i, z_i = j \mid \Theta)}{Pr(x_i \mid \Theta)} = \frac{Pr(x_i, z_i = j \mid \Theta)}{\sum_{j} Pr(x_i, z_i = j^{'} \mid \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta) \cdot Pr(z_i = j \mid \Theta)}{\sum_{j} Pr(x_i \mid z_i = j^{'}, \Theta) \cdot Pr(z_i = j^{'} \mid \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta) \cdot Pr(z_i = j \mid \Theta)}{\sum_{j} Pr(x_i \mid z_i = j^{'}, \Theta) \cdot Pr(z_i = j^{'} \mid \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta) \cdot Pr(z_i = j \mid \Theta)}{\sum_{j} Pr(x_i \mid z_i = j, \Theta) \cdot Pr(z_i = j \mid \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta) \cdot Pr(z_i = j \mid \Theta)}{\sum_{j} Pr(x_i \mid z_i = j, \Theta) \cdot Pr(z_i = j \mid \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta) \cdot Pr(z_i = j \mid \Theta)}{\sum_{j} Pr(x_i \mid z_i = j, \Theta) \cdot Pr(z_i = j \mid \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta) \cdot Pr(z_i = j \mid \Theta)}{\sum_{j} Pr(x_i \mid z_i = j, \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta) \cdot Pr(z_i = j \mid \Theta)}{\sum_{j} Pr(x_i \mid z_i = j, \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta) \cdot Pr(z_i = j \mid \Theta)}{\sum_{j} Pr(x_i \mid z_i = j, \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta) \cdot Pr(z_i = j \mid \Theta)}{\sum_{j} Pr(x_i \mid z_i = j, \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta) \cdot Pr(z_i = j, \Theta)}{\sum_{j} Pr(x_i \mid z_i = j, \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta) \cdot Pr(z_i = j, \Theta)}{\sum_{j} Pr(x_i \mid z_i = j, \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta)}{\sum_{j} Pr(x_i \mid z_i = j, \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta)}{\sum_{j} Pr(x_i \mid z_i = j, \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta)}{\sum_{j} Pr(x_i \mid z_i = j, \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta)}{\sum_{j} Pr(x_i \mid z_i = j, \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta)}{\sum_{j} Pr(x_i \mid z_i = j, \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta)}{\sum_{j} Pr(x_i \mid z_i = j, \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta)}{\sum_{j} Pr(x_i \mid z_i = j, \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta)}{\sum_{j} Pr(x_i \mid z_i = j, \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta)}{\sum_{j} Pr(x_i \mid z_i = j, \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta)}{\sum_{j} Pr(x_i \mid z_i = j, \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta)}{\sum_{j} Pr(x_i \mid z_i = j, \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta)}{\sum_{j} Pr(x_i \mid z_i = j, \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta)}{\sum_{j} Pr(x_i \mid z_i = j, \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta)}{\sum_{j} Pr(x_i \mid z_i = j, \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta)}{\sum_{j} Pr(x_i \mid z_i = j, \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta)}{\sum_{j} Pr(x_i \mid z_i = j, \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta)}{\sum_{j} Pr(x_i \mid z_i = j, \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta)}{\sum_{j} Pr(x_i \mid z_i = j, \Theta)} = \frac{Pr(x_i \mid z_i = j, \Theta)}{\sum_{j} Pr(x_i \mid z_i = j,$$

- Substitute the probabilities with the desired distribution.
- That means: the probability for sample x_i to be associated with cluster/source j.

M Step (Derive Q) - EM Receipe

$$Q(\Theta \mid \Theta^{t}) = \mathbb{E}[\mathcal{L}(X, Z \mid \Theta) \mid X, \Theta^{t}] = \sum_{Z} Pr(Z \mid X, \Theta^{t}) \log Pr(X, Z; \Theta) = \sum_{i} \sum_{j=1}^{k} Pr(z_{i} = j \mid x_{i}, \Theta^{t}) \log Pr(x_{i}, z_{i} = j, \Theta) = \sum_{i} \sum_{j=1}^{k} Pr(z_{i} = j \mid x_{i}, \Theta^{t}) \log Pr(x_{i}, z_{i} = j, \Theta) = \sum_{i} \sum_{j=1}^{k} Pr(z_{i} = j \mid x_{i}, \Theta^{t}) \log Pr(x_{i}, z_{i} = j, \Theta) = \sum_{i} \sum_{j=1}^{k} Pr(z_{i} = j \mid x_{i}, \Theta^{t}) \log Pr(x_{i}, z_{i} = j, \Theta) = \sum_{i} \sum_{j=1}^{k} Pr(z_{i} = j \mid x_{i}, \Theta^{t}) \log Pr(x_{i}, z_{i} = j, \Theta) = \sum_{i} \sum_{j=1}^{k} Pr(z_{i} = j \mid x_{i}, \Theta^{t}) \log Pr(x_{i}, z_{i} = j, \Theta) = \sum_{i} Pr(z_{i} = j \mid x_{i}, \Theta^{t}) \log Pr(x_{i}, z_{i} = j, \Theta) = \sum_{i} Pr(z_{i} = j \mid x_{i}, \Theta^{t}) \log Pr(x_{i}, z_{i} = j, \Theta) = \sum_{i} Pr(z_{i} = j \mid x_{i}, \Theta^{t}) \log Pr(x_{i}, z_{i} = j, \Theta) = \sum_{i} Pr(z_{i} = j \mid x_{i}, \Theta^{t}) \log Pr(x_{i}, z_{i} = j, \Theta) = \sum_{i} Pr(z_{i} = j \mid x_{i}, \Theta^{t}) \log Pr(x_{i}, z_{i} = j, \Theta) = \sum_{i} Pr(z_{i} = j \mid x_{i}, \Theta^{t}) \log Pr(x_{i}, z_{i} = j, \Theta) = \sum_{i} Pr(z_{i} = j \mid x_{i}, \Theta^{t}) \log Pr(x_{i}, z_{i} = j, \Theta) = \sum_{i} Pr(z_{i} = j \mid x_{i}, \Theta^{t}) \log Pr(x_{i}, z_{i} = j, \Theta) = \sum_{i} Pr(z_{i} = j \mid x_{i}, \Theta^{t}) \log Pr(x_{i}, z_{i} = j, \Theta) = \sum_{i} Pr(z_{i} = j \mid x_{i}, \Theta^{t}) \log Pr(x_{i}, z_{i} = j, \Theta) = \sum_{i} Pr(z_{i} = j \mid x_{i}, \Theta^{t}) \log Pr(x_{i}, z_{i} = j, \Theta) = \sum_{i} Pr(z_{i} = j \mid x_{i}, \Theta^{t}) \log Pr(x_{i}, z_{i} = j, \Theta) = \sum_{i} Pr(z_{i} = j \mid x_{i}, \Theta^{t}) \log Pr(x_{i}, z_{i} = j, \Theta) = \sum_{i} Pr(z_{i} = j \mid x_{i}, \Theta^{t}) \log Pr(x_{i}, z_{i} = j, \Theta) = \sum_{i} Pr(z_{i} = j \mid x_{i}, \Theta^{t}) \log Pr(x_{i}, z_{i} = j, \Theta) = \sum_{i} Pr(z_{i} = j \mid x_{i}, \Theta^{t}) \log Pr(x_{i}, z_{i} = j, \Theta) = \sum_{i} Pr(z_{i} = j \mid x_{i}, \Theta^{t}) \log Pr(x_{i}, z_{i} = j, \Theta) = \sum_{i} Pr(z_{i} = j \mid x_{i}, \Theta^{t}) \log Pr(x_{i}, z_{i} = j, \Theta) = \sum_{i} Pr(z_{i} = j \mid x_{i}, \Theta^{t}) \log Pr(x_{i}, z_{i} = j, \Theta) = \sum_{i} Pr(z_{i} = j, \Theta) = \sum_{i} Pr($$

$$\sum_{i} \sum_{j=1}^{k} r_{ij} [\log Pr(z_i = j \mid \Theta) + \log Pr(x_i \mid z_i = j, \Theta)]$$

- $r_{ij} = Pr(z_i = j | x_i, \Theta)$ (from E step)
- Substitute $Pr(x_i|z_i = j, \Theta)$ with the desired probability
- Find MLE (differentiate and compare to 0)

Gaussian Mixture Models (GMMs) as EM

· One Gaussian:

$$\mathcal{N}(x | \mu, \Sigma) = Pr(x | \mu_j, \Sigma_j) = \frac{1}{(2\pi)^{\frac{d}{2}} |\Sigma_j|^{\frac{1}{2}}} e^{-\frac{1}{2}(x - \mu_j)^T \Sigma_j^{-1}(x - \mu_j)}$$

· Gaussian Mixture:

$$Pr(x) = \sum_{j=1}^{k} \pi_{j} \mathcal{N}(x \mid \mu_{j}, \Sigma_{j})$$

- $\begin{array}{ll} \bullet & \sum_{j=1}^k \pi_j = 1 \\ \bullet & \text{The parameters of the model are: } \pi_j, \mu_j, \Sigma_j, \, \forall j \in \{1, \dots, k\} \end{array}$

· The log-likelihood of a GMM:

$$\mathcal{L}(X|\Theta) = \log \prod_{i} Pr(x_i|\Theta) = \sum_{i} \log \sum_{j=1}^{k} \pi_j \mathcal{N}(x|\mu_j, \Sigma_j)$$

- · No closed form solution and not convex!
- We introduce a latent random variable z
 - $z \in \{0,1\}^k$ a one-hot random variable indicating the source Gaussian the sample belongs to
 - $Pr(z_k) = \pi_k$ the probability of that source
 - Reminder: $\sum_{i=1}^{k} \pi_k = 1$
- The marginal probability:

$$Pr(x) = \sum_{z} p(z)p(x|z) = \sum_{j=1}^{k} \pi_{j} \mathcal{N}(x|\mu_{j}, \Sigma_{j})$$

GMM - E-Step

• The E-step computes the posterior probability of the missing data

$$Pr(z_{i} = j \mid x_{i}, \Theta) = \frac{Pr(x_{i}, z_{i} = j \mid \Theta)}{\sum_{j} Pr(x_{i}, z_{i} = j' \mid \Theta)} = \frac{\pi_{j} Pr(x_{i} \mid \mu_{j}, \Sigma_{j})}{\sum_{j} \pi_{j} Pr(x_{i} \mid \mu_{j'}, \Sigma_{j'})} = \frac{\pi_{j} \mid \Sigma_{j} \mid -\frac{1}{2} e^{-\frac{1}{2} (x_{i} - \mu_{j})^{T} \Sigma_{j}^{-1} (x_{i} - \mu_{j'})}{\sum_{j} \pi_{j'} \mid \Sigma_{j'} \mid -\frac{1}{2} e^{-\frac{1}{2} (x_{i} - \mu_{j'})^{T} \Sigma_{j'}^{-1} (x_{i} - \mu_{j'})}}$$

• Denote: $r_{ij} = Pr(z_i = j | x_i, \Theta)$

GMM - Calculate $Q(\Theta; \Theta^t)$

$$\begin{split} Q(\Theta \,|\, \Theta^I) &= \mathrm{E}[\mathcal{L}(X,Z \,|\, \Theta) \,|\, X, \Theta^I] = \sum_{Z} Pr(Z \,|\, X, \Theta^I) \mathrm{log} Pr(X,Z;\Theta) = \sum_{i} \sum_{j=1}^k Pr(z_i = j \,|\, x_i, \Theta^I) \mathrm{log} Pr(x_i,z_i = j,\Theta) = \\ & \sum_{i} \sum_{j=1}^k r_{ij} [\mathrm{log} Pr(z_i = j \,|\, \Theta) + \mathrm{log} Pr(x_i \,|\, z_i = j,\Theta)] = \\ & \sum_{i} \sum_{j=1}^k r_{ij} [\mathrm{log} \pi_j + \mathrm{log} Pr(x_i \,|\, \mu_j, \Sigma_j)] = \\ & \sum_{i} \sum_{j=1}^k r_{ij} \mathrm{log} \pi_j - \frac{1}{2} \sum_{j=1}^k \mathrm{log} \,|\, \Sigma_j \,|\, \sum_{i} r_{i,j} - \frac{1}{2} \sum_{i} \sum_{j=1}^k r_{ij} (x_i - \mu_j)^T \Sigma_j^{-1}(x_i - \mu_j) + Const \end{split}$$

GMM - M-Step

- To maximize $Q(\Theta; \Theta^t)$ with respect to μ_{j^*} we set the gradient to zero.

• Reminder:
$$\frac{\partial}{\partial s}(x - As)^T W(x - As) = -2A^T W(x - As)$$

Derive:

$$\frac{\partial}{\partial \mu_j} Q(\Theta; \Theta^t) = \sum_{i=1}^n r_{ij} \Sigma_j^{-1} (x_i - \mu_j) = 0 \rightarrow \hat{\mu}_j = \frac{\sum_{i=1}^n r_{ij} x_i}{\sum_{i=1}^n r_{ij}}$$

· Similarly:

$$\hat{\Sigma}_{j} = \frac{\sum_{i=1}^{n} r_{ij} (x_{i} - \mu_{j}) (x_{i} - \mu_{j})^{T}}{\sum_{i=1}^{n} r_{ii}}$$

- To maximize $Q(\Theta; \Theta^t)$ with respect to π_i :
 - Use **Lagrange** multiplier:

$$\begin{aligned} & \circ & \max \ Q(\Theta; \, \Theta^t) \ \text{s.t.} \ \sum_j \pi_j = 1 \ \Longleftrightarrow \\ & \circ & \mathcal{L} = Q(\Theta; \, \Theta^t) + \lambda (1 - \sum_j \pi_j) \end{aligned}$$

• Find an expression for λ by summing all partial derivatives of π_i :

$$\sum_{i} r_{ij}^{(t)} = \lambda \pi_j \rightarrow \sum_{j} \sum_{i} r_{ij}^{(t)} = \lambda \sum_{j} \pi_j \rightarrow \lambda = n$$

$$\circ \ \, \sum_{j} \sum_{l} r_{ij}^{(t)} = \sum_{j} \sum_{l} Pr(z_i = j \,|\, x_i, \Theta^t) = \sum_{l} \frac{\sum_{j} Pr(x_i, z_i = j \,|\, \Theta)}{\sum_{j'} Pr(x_i, z_i = j^{'} \,|\, \Theta)} = \sum_{i=1}^n 1 = n$$

• Substituting λ back in the Lagrangian derivative:

$$\frac{\partial \mathcal{L}}{\partial \pi_j} = \sum_{i} \frac{r_{ij}}{\pi_j} - \lambda = 0 \longrightarrow \hat{\pi}_j = \frac{\sum_{i=1}^{n} r_{ij}}{n}$$

• To sum up:

$$\hat{\mu}_j = \frac{\sum_{i=1}^n r_{ij} x_i}{\sum_{i=1}^n r_{ij}}$$

$$\hat{\Sigma}_{j} = \frac{\sum_{i=1}^{n} r_{ij} (x_{i} - \mu_{j}) (x_{i} - \mu_{j})^{T}}{\sum_{i=1}^{n} r_{ij}}$$

$$\hat{\pi}_j = \frac{\sum_{i=1}^n r_{ij}}{n}$$

Bernoulli Mixture Models (BMMs) as EM

- We have k coins such that:
 - The probability of observing *heads* with the j^{th} coin is p_i .
 - We do not observe which coin was used.
 - We only observe $x_i \in \{0, 1\}$, which records whether we see a *heads* or *tails*.
- Let $z_i \in \{1, \dots, k\}$ be the **missing information** of which coin was used on each flip (in other words, the *source* like in the GMM case).
 - The probability of using the j^{th} coin is $Pr(z_i = j) = \pi_j$ (which is a *parameter*)
- The complete data is given by (X, Z)
 - Using the **law of total probability**, the (marginal) probability of the observed data X:

$$Pr(X) = \sum_{j} Pr(X|Z=j)Pr(Z=j)$$

■ Thus, the likelihood of the full data set (incomplete likelihood) is:

$$\mathcal{L}(X|\Theta) = \prod_{i} \sum_{j} Pr(x_{i}|z_{i} = j) Pr(z_{i} = j) = \prod_{i} \sum_{j} \pi_{i} p_{j}^{x_{i}} (1 - p_{j})^{1 - x_{i}}$$

$$\circ \ \Theta = (\pi, p)$$

BMM - E-Step

. The E-step computes the posterior probability of the missing data

$$Pr(z_{i} = j \mid x_{i}, \Theta) = \frac{Pr(x_{i}, z_{i} = j \mid \Theta)}{\sum_{j} Pr(x_{i}, z_{i} = j' \mid \Theta)} = \frac{\pi_{j} Pr(x_{i} \mid p_{j})}{\sum_{j} \pi_{j} Pr(x_{i} \mid p_{j'})} = \frac{\pi_{j} p_{j}^{x_{i}} (1 - p_{j})^{1 - x_{i}}}{\sum_{j} \pi_{j} p_{j}^{x_{i}} (1 - p_{j'})^{1 - x_{i}}}$$

• Denote: $r_{ij} = Pr(z_i = j | x_i, \Theta)$

BMM - Calculate $Q(\Theta; \Theta^t)$

$$\begin{split} Q(\Theta \mid \Theta^t) &= \mathbb{E}[\mathcal{L}(X,Z \mid \Theta) \mid X, \Theta^t] = \sum_{Z} Pr(Z \mid X, \Theta^t) \log Pr(X,Z;\Theta) = \sum_{i} \sum_{j=1}^k Pr(z_i = j \mid x_i, \Theta^t) \log Pr(x_i,z_i = j, \Theta) = \\ &\sum_{i} \sum_{j=1}^k r_{ij} [\log Pr(z_i = j \mid \Theta) + \log Pr(x_i \mid z_i = j, \Theta)] = \\ &\sum_{i} \sum_{j=1}^k r_{ij} [\log \pi_j + \log Pr(x_i \mid p_j)] = \\ &\sum_{i} \sum_{j=1}^k r_{ij} \log \pi_j + \sum_{i} \sum_{j=1}^k r_{ij} \log \left(p_j^{x_i} (1 - p_j)^{1 - x_i} \right) = \\ &\sum_{i} \sum_{j=1}^k r_{ij} \log \pi_j + \sum_{i} \sum_{j=1}^k r_{ij} \log \left(p_j^{x_i} (1 - x_i) \log (1 - p_j) \right) \end{split}$$

BMM - M-Step

- To maximize $Q(\Theta; \Theta^t)$ with respect to p_i , we set the gradient to zero.
- · Derive:

$$\frac{\partial}{\partial p_j}Q(\Theta;\Theta^l) = \sum_{i=1}^n r_{ij} \left(\frac{x_i}{p_j} - \frac{1-x_i}{1-p_j}\right) = 0 \rightarrow \hat{p}_j = \frac{\sum_{i=1}^n r_{ij}x_i}{\sum_{i=1}^n r_{ii}}$$

- To maximize $Q(\Theta; \Theta^t)$ with respect to π_i :
 - Use Lagrange multiplier:

•
$$\max Q(\Theta; \Theta^t)$$
 s.t. $\sum_j \pi_j = 1 \iff$
• $\mathcal{L} = Q(\Theta; \Theta^t) + \lambda(1 - \sum_j \pi_j)$

• Find an expression for λ by summing all partial derivatives of π_i :

$$\sum_{i} r_{ij}^{(t)} = \lambda \pi_j \rightarrow \sum_{i} \sum_{j} r_{ij}^{(t)} = \lambda \sum_{j} \pi_j \rightarrow \lambda = n$$

$$\circ \ \, \sum_{j} \sum_{l} r_{ij}^{(t)} = \sum_{j} \sum_{i} Pr(z_{i} = j \, | \, x_{i}, \Theta^{t}) = \sum_{l} \frac{\sum_{j} Pr(x_{i}, z_{i} = j \, | \, \Theta)}{\sum_{j} Pr(x_{i}, z_{i} = j^{'} \, | \, \Theta)} = \sum_{i=1}^{n} 1 = n$$

• Substituting λ back in the Lagrangian derivative

$$\frac{\partial \mathcal{L}}{\partial \pi_j} = \sum_{i} \frac{r_{ij}}{\pi_j} - \lambda = 0 \rightarrow \hat{\pi}_j = \frac{\sum_{i=1}^{n} r_{ij}}{n}$$

• To sum up:

$$\hat{p}_{j} = \frac{\sum_{i=1}^{n} r_{ij} x_{i}}{\sum_{i=1}^{n} r_{ii}}$$

$$\hat{\pi}_j = \frac{\sum_{i=1}^n r_{ij}}{n}$$

- If all $r_{ij} = \{0, 1\}$, that is, deterministic, then:
 - The component labels, z_i , are **known**
 - The above update equations reduce to the standard formulas for *binomial distribution*.

Relation to K-Means: K-Means as "Hard GMM"

• Recall the E-Step for GMM:

$$Pr(z_{i} = j \mid x_{i}, \Theta) = \frac{Pr(x_{i}, z_{i} = j \mid \Theta)}{\sum_{j} Pr(x_{i}, z_{i} = j' \mid \Theta)} = \frac{\pi_{j} Pr(x_{i} \mid \mu_{j}, \Sigma_{j})}{\sum_{j} \pi_{j} Pr(x_{i} \mid \mu_{j'}, \Sigma_{j'})} = \frac{\pi_{j} e^{-\frac{1}{2}(x_{i} - \mu_{j})^{T} \Sigma_{j}^{-1}(x_{i} - \mu_{j})}}{\sum_{j} \pi_{j} e^{-\frac{1}{2}(x_{i} - \mu_{j})^{T} \Sigma_{j}^{-1}(x_{i} - \mu_{j'})}}$$

• Let's assume all the Gaussians have the same $\Sigma = \epsilon I$:

$$Pr(z_{i} = j \mid x_{i}, \Theta) = \frac{Pr(x_{i}, z_{i} = j \mid \Theta)}{\sum_{j} Pr(x_{i}, z_{i} = j' \mid \Theta)} = \frac{\pi_{j}e^{-\frac{1}{2\epsilon}||(x_{i} - \mu_{j})||_{2}^{2})}}{\sum_{j} \pi_{j}e^{-\frac{1}{2\epsilon}||(x_{i} - \mu_{j})||_{2}^{2}}}$$

- At the limit $\epsilon \to 0$: $Pr(z_i = j \mid x_i, \Theta) = 1$ for $j = argmin\{x_i \mu_j\}$ and $Pr(z_i = j \mid x_i, \Theta) = 0$ for all others.
- Thus:

$$\begin{cases} r_{ij} = 1 & \text{if } j = argmin_j \mid |x_i - \mu_j| \mid \frac{2}{2} \\ r_{ij} = 0 & \text{else} \end{cases}$$

• The GMM equations are now identical to the K-Means' eqautions:

$$\hat{\mu}_j = \frac{\sum_{i=1}^n r_{ij} x_i}{\sum_{i=1}^n r_{ij}}$$

$$\hat{\pi}_j = \frac{\sum_{i=1}^n r_{ij}}{n}$$

• The π s are not really required.
